

Your best shot at good health

Preventing disease protects you and your community

You take care of yourself and you're pretty careful about what you eat. But are you up to date on your vaccines? Even as an adult, health screenings and shots are just as important as exercise at helping you stay healthy. Why?

- Immunity from your childhood vaccines can fade over time. You might need a booster shot.
- Newer vaccines can help protect against things like chickenpox and the virus that causes cervical cancer.
- You may have missed some of your shots when you were a kid. Getting childhood illnesses as an adult can be even harder on your body.

The good news is that it isn't too late to catch up. Not only will you protect yourself and your family, but you could also help to stop the spread of illness worldwide. And that's a battle worth fighting.

How vaccines work with your immune system

When you're sick, your body's immune system kicks in to fight off germs.¹ Your immune system has a memory. It remembers what you've been exposed to before to help protect you the next time around. Some germs are so strong that they can overwhelm the immune system. That's where vaccines come into play. Because the germs in vaccines have been weakened or killed, they don't cause an illness. But they do cause your body to build up immunity. That helps you fight off the germs better.¹ Vaccine-preventable diseases can be deadly without the vaccine's boost to your immune system.

Before we had vaccines, the only way to become immune to an illness was to get the illness. That could be serious — or even deadly. Being vaccinated is a way to build up immunity with less risk.¹
